Cross-Chain Investigations

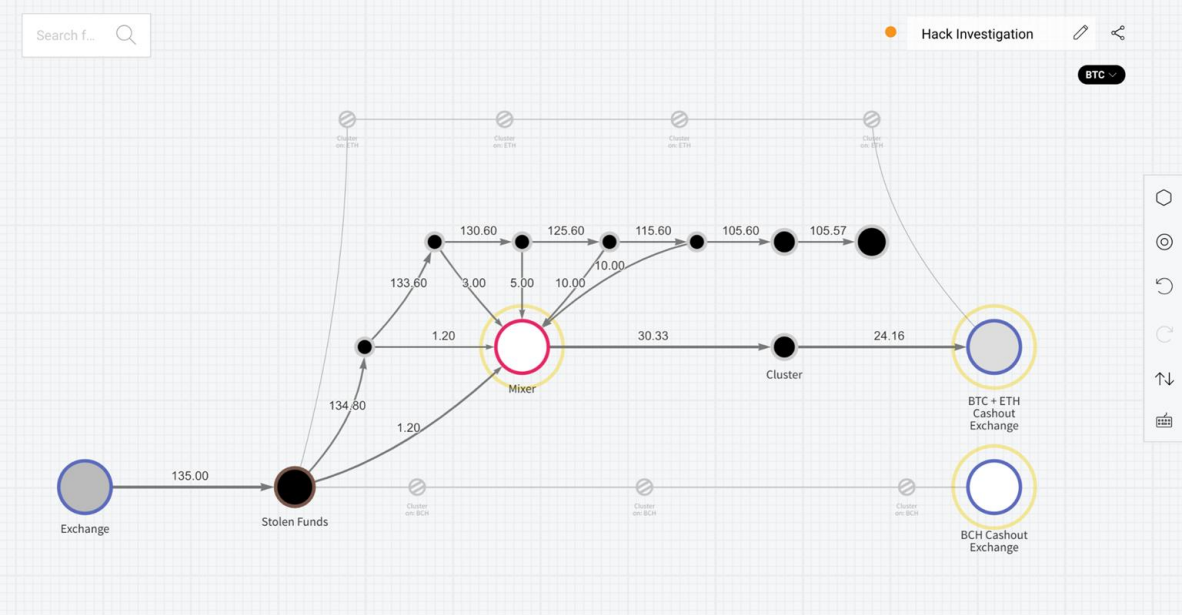

Investigate cross-chain illicit activity seamlessly

As the cryptocurrency industry grows, blockchain analysis needs to adapt to accommodate the changing nature of its use. With the DeFi boom, criminals are taking advantage of the multitude of coins available to swap tokens in an attempt to obfuscate funds.

Investigators and compliance officers are increasingly encountering cases that require them to trace funds across different blockchains. Chainalysis Cross-chain Investigations accelerates analysis by visualizing flow of funds across multiple blockchains in a single graph and enriching information on smart contract transactions.

Tracing multiple assets on a single graph

When a Reactor graph contains clusters with activity across multiple cryptocurrencies, a drop down menu appears under the graph name listing all associated assets. Selecting an asset from the drop down menu allows users to toggle between different blockchains in the same graph, and visualize flow of funds per cryptocurrency. Additionally, Cross-chain Investigations makes it easy to identify swapping activity and on/off ramp addresses.

Holistic view of a cluster's activity

Cross-Chain Investigations streamlines analysis for all Chainalysis Reactor users. Law enforcement agencies can create a file representing all of a suspect's activity and then import into Reactor as a single custom cluster. Additionally, compliance officers using Chainalysis KYT can export a user's activity across assets as a customer cluster. This feature allows you to easily add a custom cluster's multi-asset activity and investigate it in one graph.

More Visibility into DeFi and NFT Activity

Enriched Ethereum Transaction View

Reactor provides an enriched transaction view for Ethereum transactions. When an Ethereum cluster is selected, the transaction panel provides information on what is happening on the blockchain, such as token swaps and smart contracts.

The transaction panel clearly identifies activity such as NFTs, swaps, and flash loans. Additionally, it shows all transaction information for all assets being used by that cluster, even ones that are not yet supported in Chainalysis Reactor.
